Abstract

Background – COPD and Asthma patients who develop raised PCO₂ levels causing decreased consciousness are frequently admitted in ICU for respiratory support. Non Invasive Ventilation is the latest technology used by intensivists to bring the PCO₂ level of such patients to a physiologically acceptable value. This technique by passes the adverse effects of Invasive Ventilation along with sedation and muscle paralysis. Patients admitted to ICU are already anxious and irritable and unwilling to accept NIV mask because of claustrophobia. Rapid improvement in such patients' consciousness level can improve their cognitive factors such as perception, memory, attention, learning, visuospatial and construction abilities and language skills along with emotional and social capabilities leading to overall improvement in their quality of life. NIV mask tolerance can be improved by proper psychological counseling of such patients and by teaching them the Heartfulness relaxation method. Heartfulness relaxation method is a self learning heart based technique using the concept of auto suggestion and imagination. A cooperative patient is made to listen the heartfulness relaxation method audio and by self suggesting he/she relaxes his/her body and mind to get properly accustomed to NIV mask wearing.

OBJECTIVES - the primary objective of this study is to evaluate the effects of proper NIV mask adherence and acceptance by relaxation and psychological guidance leading to improved cognitive functions in drowsy COPD and Asthmatic patients admitted in ICU. The secondary objectives are to study the improvement in physiology along with SPO₂% values in such patients.

Statistical Analysis-Data analysis was performed using SPSS 20 (IBM SPSS Statistics) for windows. The Addenbrooke's Cognitive Examination Score was compared between the two groups by repeated measure of analysis of variance. P value of <0.05 was considered statistically significant.

Result and Conclusion-Patients in the Cases group (group A) showed better cognition and acceptability of NIV mask voluntarily as compared to the control group (group B).

Keywords-NIV mask, COPD, Addenbrooke's Cognitive Examination Score, Systolic Blood Pressure, Diastolic Blood Pressure, Pulse Rate, SPO₂%.

INTRODUCTION-

COPD and Asthma patients who develop raised PCO₂ levels causing decreased consciousness are frequently admitted in ICU for respiratory support. Non Invasive Ventilation is the latest technology used by intensivists to bring the PCO₂ level of such patients to a physiologically acceptable value.

This technique by passes the adverse effects of Invasive Ventilation along with sedation and muscle paralysis.

Patients admitted to ICU are already anxious and irritable and unwilling to accept NIV mask because of claustrophobia. Rapid improvement in such patients' consciousness level can improve their cognitive factors such as perception, memory, attention, learning, visuospatial and construction abilities and language skills along with emotional and social capabilities leading to overall improvement in their quality of life.

NIV mask tolerance can be improved by proper psychological counseling of such patients and by teaching them the Heartfulness relaxation method.

A PHYSIOPSYCHOLOGICAL INTERVENTION TO PROMOTE ACCEPTANCE AND ADHERENCE TO NON-INVASIVE VENTILATION IN SEMICONSCIOUS PATIENTS ADMITTED TO ICU FOR HIGHER PCO₂ LEVELS; A RANDOMISED CONTROLLED STUDY

Heartfulness relaxation method is a self learning heart based technique using the concept of auto suggestion and imagination. A cooperative patient is made to listen the heartfulness relaxation method audio and by self suggesting he/she relaxes his/her body and mind to get properly accustomed to NIV mask wearing .

METHODOLOGY-

This study was carried out in SJPMC Medical college and attached RBM Hospital (Bharatpur) Medical ICU, where after proper approval from the Ethical committee of this institution and after obtaining proper informed consent by the patients relatives, all COPD and Asthma patients who were admitted due to a raised PCO₂ level and decreased consciousness, were admitted and the Non Invasive Ventilation treatment using Bi PAP level of 14 cm H₂O/ 6 cm H₂O of the IPAP / EPAP level and the treatment was started.

All the multipara monitors including NIBP, SPO₂, ECG along with heart rate monitoring were applied to the patients. The medical treatment was carried out by the medical team.

These patients were randomly divided into cases group and controls group (Group A and Group B respectively).

In the group A after the patients regained improvement in consciousness level were made to listen to heartfulness relaxation audio along with their proper psychological counseling .

In the group B, no such activity was carried out.

These patients were treated by NIV for 4 hours initially and then 4 hours gap and then intermittently 2 hours treatment and 4 hours gap until their PCO₂ level was brought down to 94 which is a physiologically acceptable level in such COPD, Asthma patients.

Throughout the whole treatment, patients of the group A were counseled and taught to relax their mind to accept the NIV mask properly.

The vital values were obtained during admission and every 12 hourly after that The Addenbrooke's Cognitive Examination score was taken at the time of admission and then every 24 hours thereafter.

All the vitals and SPO₂ levels were also recorded at the same time intervals. Informed consent by obtained by the close relatives of patients.

All patients received regular nebulised bronchodilators including Salbutamol, Ipratropium Bromide and intravenous Steroids. All patients also received antibiotics. Spontaneously breathing patients were administered controlled oxygen therapy (5 to 10 Litres per minute) during NIV free period.

Endotracheal intubation was performed for standard indications like respiratory arrest, deteriorating level of consciousness, exhaustion, progressive hypoxemia, hypercapnea, and deteriorating acidemia despite maximal level of medical treatment.

Exclusion criteria-

patients who were to be taken on invasive ventilation, who were taken on vasomotor support, who were suffering with any other comorbid medical illness like Diabetes, Hypertension, Heart disease, previous stroke, etc. and patients on any kind of psychiatric treatment and who died during the study were excluded from it.

Patients with underlying COPD, Asthma admitted with another primary admitting diagnosis (Accident, Stroke, Acute Myocardial Infarction) were excluded from the study. Similarly patients with acute respiratory failure secondary to bronchiectasis, bronchial asthma, tuberculosis, pneumothorax, pulmonary embolism, pulmonary oedema and neurologic/myopathic causes were also excluded.

RESULTS –

During the study period of one year, total 60 patients were enrolled for clinical evaluation for study.

They were randomized into two groups.

Demographic variables (age, sex) were comparable in both groups ($P > 0.05$). Vital parameters were comparable in both groups with no statistically significant differences ($P > 0.05$).

Discussion-

1. S. Kumar et.al. have shown the benefit of NIV/BIPAP to be beneficial in COPD patients.
2. E. Clini et.al. have demonstrated the improvement in quality of life of COPD patients who were on long term NIV therapy. According to them compared with long term oxygen therapy alone, the addition of Noninvasive Positive Pressure Ventilation to long term oxygen therapy in stable chronic obstructive pulmonary disease patients with chronic ventilator failure :1) slightly decreased the trend to carbondioxide retention in patients receiving oxygen. 2) improved dyspnoea and health related quality of life.
3. R. Rangappa et.al. have shown the importance of ABCDEF bundle as the solution for delirium in ventilated patients in the ICU. Regular family bonding and early mobilization are the key concepts in his study.
4. Gopi C. Khilnani et.al. show the importance of stepwise protocol for weaning patients from Non Invasive Ventilation in which early recovery of consciousness is the key factor.
